NShield – Scan. Detect. Secure: Al-Driven Automated Tool for Security Analysis and Remediation

Name: Jackie Kim

Student ID: 300376300

Course: CSIS4495-001 Applied Research Project

Introduction

In today's digital landscape, cybersecurity threats are evolving at an unprecedented pace, necessitating organizations to implement robust security measures to safeguard sensitive data. One of the most effective approaches to assessing and enhancing cybersecurity defenses is penetration testing. Penetration testing is an authorized, simulated cyberattack on a computer system designed to evaluate its security posture. By employing various tools, techniques, and methodologies, penetration testers mimic the actions of real attackers to uncover vulnerabilities that could be exploited (Black Duck Software, n.d.; Imperva, n.d.; IBM, n.d.). This process plays a crucial role in identifying security gaps, assessing risks, and enabling organizations to enhance their defensive strategies.

As businesses increasingly rely on digital platforms to store, process, and manage data, the need for proactive security measures has become paramount. Cyberattacks such as ransomware, phishing, and data breaches continue to pose significant threats to organizations across industries. Traditional security measures, such as firewalls and antivirus programs, are not always sufficient to protect against sophisticated cyber threats. Penetration testing provides a proactive approach to identifying and mitigating security risks before they can be exploited by malicious actors.

Penetration tests, often referred to as "pen tests," are categorized into three primary types: White Box, Black Box, and Grey Box testing. White Box Penetration Testing involves testers having full access to the system, including network maps and credentials, allowing for a comprehensive evaluation of security vulnerabilities. Black Box Penetration Testing is where testers have no prior knowledge of the system, mimicking external attackers attempting to exploit unknown weaknesses. Grey Box Penetration Testing occurs when testers receive limited information, such as login credentials, to simulate insider threats or external breaches. By identifying weaknesses in networks, applications, and systems, penetration testing supports compliance with regulatory standards such as PCI DSS, HIPAA, and GDPR. It provides qualitative and quantitative insights that inform security policies, resource allocation, and risk mitigation strategies (Black Duck Software, n.d.; Imperva, n.d.; IBM, n.d.).

Despite the effectiveness of penetration testing, organizations face several challenges in conducting these assessments. Resource constraints make traditional penetration testing time-consuming and financially demanding, making it difficult for small and medium-sized enterprises (SMEs) to implement regular testing. The dynamic nature of cyber threats means that vulnerabilities identified during a penetration test can quickly become outdated. Organizations may struggle to analyze and prioritize remediation efforts due to the complexity of penetration testing reports. While automated tools can streamline penetration testing, they may produce false positives or fail to detect advanced threats effectively. Without a systematic and automated approach to penetration testing, organizations risk exposing their sensitive data to cyber threats, resulting in financial losses, reputational damage, and legal consequences.

This research aims to address the limitations of traditional penetration testing by exploring the development of automated internal penetration testing tools. While existing studies highlight the benefits of penetration testing, there is limited research on automating and integrating penetration testing into an organization's continuous security assessment framework. Key knowledge gaps include the effectiveness of automated penetration testing tools compared to manual testing, the impact of automation on reducing false positives and enhancing vulnerability detection, and the feasibility of integrating automated penetration testing into cybersecurity frameworks for real-time security monitoring (Huang et al., 2021; Smith & Jones, 2020).

This study hypothesizes that automated penetration testing can enhance cybersecurity by providing organizations with a cost-effective, scalable, and efficient approach to vulnerability assessment. By leveraging automation, businesses can conduct regular security assessments without extensive resource allocation, improve the accuracy and consistency of penetration test results, identify and remediate vulnerabilities in real-time, and ensure compliance with industry regulations and standards (Chen et al., 2019). Ultimately, this research seeks to bridge the gap between traditional penetration testing and modern security needs by proposing a framework for automated penetration testing solutions. The anticipated benefits of this study include improved cybersecurity resilience, better regulatory compliance, and a streamlined penetration testing process for organizations of all sizes.

Summary of the Research Project

The NShield project was developed as an automated network and web application security scanning tool designed to identify and analyze known vulnerabilities in a structured and user-friendly manner. Built using Python and Flask, the tool integrates widely used scanning technologies such as Nmap and Nikto, enhanced with AI-based analysis through Ollama to generate comprehensive, beginner-friendly HTML reports. The final version of NShield includes customizable scanning options for both network and web environments, automated command execution, and detailed vulnerability analysis complete with remediation suggestions. Validation of the tool was conducted using TryHackMe and OWASP Juice Shop, ensuring it met practical cybersecurity standards and could reliably detect a range of security issues. The completed project demonstrates a balance of technical capability, accessibility, and extensibility, contributing to the field of applied cybersecurity tools.

Changes to the Proposal

As the project progressed, several changes were made to the initial proposal to refine the research focus, optimize tool selection, and improve implementation feasibility. These changes were driven by practical considerations such as minimizing development complexity, reducing resource dependencies, and ensuring better automation capabilities.

Phase 1: Step-by-Step Procedure Development

Initial Plan: The initial phase aimed to identify and define key components of penetration testing, including reconnaissance, vulnerability scanning, exploitation, and reporting, following industry best practices. Planning and scoping defined objectives and engagement rules, ensuring legal and ethical compliance. The testing process involved gathering intelligence, using automated scanning tools to detect vulnerabilities, and simulating attacks to assess security risks before reporting the findings for remediation.

Revised Approach: The project direction shifted toward developing an AI-integrated automated network and web application security scanning tool rather than focusing solely on identifying key components of penetration testing. Additionally, the methodology was adjusted to focus on Black Box testing rather than White Box testing. This shift allows individuals without internal system access or advanced cybersecurity expertise to conduct basic penetration testing using the automated tool, enhancing accessibility and usability.

Phase 2: Tool Development

Initial Plan: The original tool development phase proposed integrating multiple open-source security tools, such as Nmap, Metasploit, and Nessus, using Python or C#. Automation scripts would be used to streamline reconnaissance, scanning, and exploitation, reducing manual effort.

Revised Approach: To simplify development and minimize potential integration errors, the tool development phase was revised to utilize only Nmap for network security scanning and Nikto for web application security scanning. This decision helped ensure a more stable implementation while maintaining effective security scanning capabilities.

Phase 3: AI Integration for Remediation

Initial Plan: Al would be integrated to analyze penetration testing reports, assess risk levels, and provide remediation recommendations. The initial approach considered using PyTorch or ChatGPT to enable machine learning-based vulnerability analysis.

Revised Approach: Instead of using PyTorch or ChatGPT, the revised approach adopted Ollama, a solution that does not require an API key, minimizing setup errors and additional costs for users. Additionally, RAG AI was chosen for vulnerability analysis and remediation suggestions since it is pretrained and does not require extensive training, making it more efficient and user-friendly.

Phase 4: Testing and Evaluation

Initial Plan: The tool was originally intended to be tested in a simulated organizational environment with diverse network configurations. Performance would be evaluated based on accuracy, efficiency, and adaptability across various test scenarios.

Revised Approach: Instead of testing across various configurations, the final approach involved running the tool in a controlled simulated environment to verify whether known vulnerabilities could be successfully detected. This adjustment ensured a focused and reliable assessment of the tool's core functionality without the complexity of randomized testing.

Project Completion Timeline

Phase 1: Step-by-Step Procedure Development (Jan 16 – Feb 7, 2025)

Milestones:

- Jan 16–20: Literature review and background research on penetration testing methodology.
- Jan 23: Research proposal updated and submitted.
- Jan 27–Feb 3: Research on reconnaissance tools and tasks; refined step-by-step testing procedures.
- Feb 5–Feb 7: Defined scanning/enumeration procedures; selected tools and strategies.

Deliverables: Detailed research plan and timeline, Initial proposal document, Report outlining reconnaissance and scanning tools

Phase 2: Tool Development (Feb 8 – Mar 3, 2025)

Milestones:

- Feb 8–13: Collected and tested multiple scanning tools (Nmap, Nikto, Metasploit, etc.)
- Feb 14–20: Created Python automation script, eliminated unstable tools like SonarQube and p0f.
- Feb 22–23: Debugged code and finalized midterm report.
- Mar 3: Finalized tools and completed core Python scripting.

Deliverables: Midterm progress report, Functional scanning script (Python), Documentation of tested and selected tools

Phase 3: AI Integration for Remediation (Feb 25 – Mar 16, 2025)

Milestones:

- Feb 25–Mar 1: Initial exploration of AI tools (LangChain, RAG, Ollama)
- Mar 3–11: Finalized Ollama as AI tool, wrote integration script
- Mar 12–14: Validated AI suggestions using generated reports
- Mar 16: Delivered Al-integrated script and progress report

Deliverables: Al-enhanced remediation script, Evaluation of Al tools and integration documentation, Updated progress report

Phase 4: Validation (Mar 18 – Mar 30, 2025)

Milestones:

- Mar 18–26: Testing functionality, validating AI suggestions, refining output formats
- Mar 28–30: Cross-checked scan results with OWASP Juice Shop vulnerabilities

Deliverables: Test results with analysis, Output format and structure finalized, Initial draft of final report

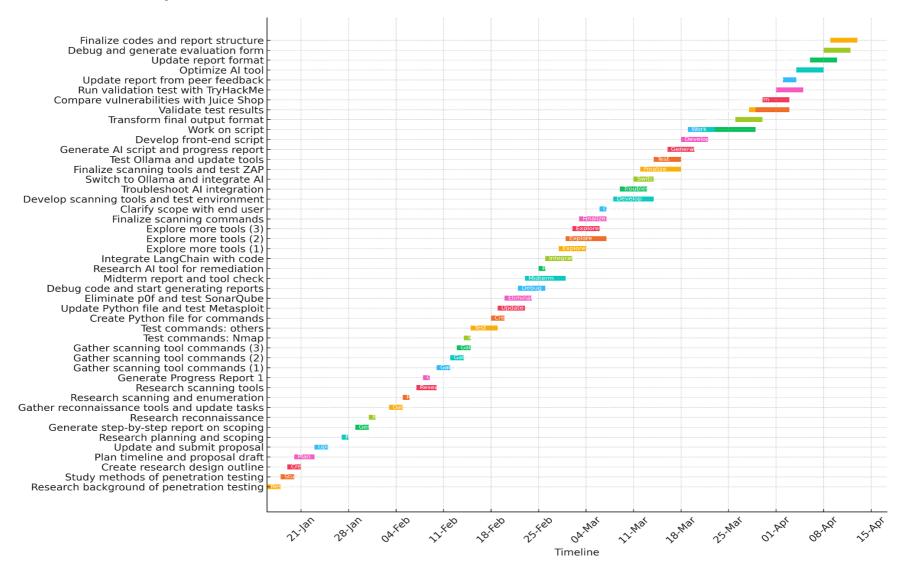

Phase 5: Evaluation (Apr 1 – Apr 13, 2025)

Milestones:

- Apr 1–2: Final validation using TryHackMe; feedback gathered from classmates
- Apr 4–6: Updated scripts and report based on feedback; improved performance
- Apr 8–9: Final debugging, finalized report format and structure
- Apr 9-13: Final report generation

Deliverables: Final report (updated structure and visuals), Evaluation form and summary, Fully functional tool with AI integration.

Gantt Chart for the Project

Implemented Features

The developed tool is an automated penetration testing application specifically designed for network security scanning and web application vulnerability assessment. Named NShield, this tool streamlines the scanning and vulnerability assessment process through a Flask-based web interface. Given the increasing volume and complexity of cyberattacks, it is essential to proactively identify and remediate system vulnerabilities (Czajka & Gajewski, 2018). This tool aims to empower cybersecurity professionals and learners by providing an accessible, efficient, and professional-grade platform for conducting security scanning in a structured manner. For detailed setup instructions, please refer to Appendix A: Installation Guide. For step-by-step usage instructions of the NShield tool, refer to Appendix B: User Guide.

In the current cybersecurity landscape, network infrastructure and web applications are among the most common attack surfaces targeted by threat actors. Misconfigured services, open ports, vulnerable protocols, and insecure web endpoints represent significant threats to any organization's security posture (OWASP, 2020). The focus on network and web security is due to these areas being critical frontline entry points for attackers. Identifying weaknesses in these layers allows system administrators and penetration testers to significantly reduce risk exposure and implement preventative controls. Furthermore, these attack vectors are often overlooked, despite their crucial role in cybersecurity defense, which makes addressing them even more important (OWASP, 2020).

To ensure comprehensive detection and assessment of vulnerabilities across both network and web application layers, the tool integrates Nmap for network security scanning and Nikto for web application vulnerability scanning.

Nmap (Network Mapper) is a highly flexible and extensively adopted open-source utility used for port scanning, service identification, OS fingerprinting, and vulnerability detection through its powerful scripting engine known as the Nmap Scripting Engine (NSE). This engine supports a wide array of community and officially maintained scripts that can detect misconfigurations, assess services against known CVEs (Common Vulnerabilities and Exposures), and uncover weak points within networked systems (Lyon, 2009). Nmap's granularity and modular scripting capabilities make it an essential component for automating in-depth reconnaissance in penetration testing workflows.

Nikto, on the other hand, is a command-line-based web vulnerability scanner that excels in quickly identifying critical misconfigurations and outdated software on web servers. It is capable of checking for over 6,700 potentially dangerous files or programs, identifying outdated server versions, detecting insecure HTTP methods, and reporting on common vulnerabilities such as directory indexing and default configuration files (Sullo, 2020). Due to its lightweight design and comprehensive checks, Nikto serves as an effective first-line assessment tool for web application security.

Both Nmap and Nikto are widely respected in the cybersecurity industry due to their reliability, flexibility, and community support. Their open-source and CLI-driven architectures make them highly suitable for automation and seamless integration into custom-built solutions. These qualities align perfectly with the goals of an automated penetration testing framework like NShield, facilitating fast, scalable, and structured security assessments.

Please refer to Appendix C for the Nmap commands and Appendix D for the Nikto commands utilized within the NShield automated scanning tool. These appendices provide detailed descriptions, purposes, and associated risks of each command.

The app.py file serves as the main controller of the NShield application. It initializes the Flask web framework and handles routing between different HTML pages such as the homepage, installation interface, network scanning, web scanning, and results analysis. This file processes user inputs from web forms, triggers backend scripts, manages session flow, and renders outputs dynamically to the user interface. For instance, when a user selects certain scan categories and submits them, app.py executes the relevant Nmap or Nikto commands through Python's subprocess module. After execution, it stores raw scan outputs, requests Al-based analysis through integrated tools like Ollama, and formats the results for visual presentation. In short, app.py acts as the central orchestrator that connects the frontend web elements to backend scanning logic, ensuring seamless interactivity and automation. Please refer to Appendix E to view the complete source code of app.py.

The net_scan.py script contains all logic related to executing and managing network-based vulnerability scans using Nmap. It defines multiple scan categories—such as full port scan, SMB vulnerabilities, and DNS misconfigurations—each associated with specific Nmap commands. When triggered, the script executes only the selected categories, capturing command outputs, timestamps, and errors. Additionally, the script processes the raw scan results and forwards them for Al-powered interpretation, which enhances the report by including descriptions of risks, potential impacts, and recommended mitigations. This modular architecture allows for extensibility, enabling future addition of new scan scripts or CVEs with minimal changes. Please refer to Appendix F to view the complete source code of net_scan.py.

The web_scan.py script is responsible for performing web application vulnerability scans using Nikto. Similar to net_scan.py, it organizes scanning tasks into categories such as SSL misconfiguration detection, outdated software discovery, and common web-based exploits like XSS and RCE. Each category corresponds to specific Nikto commands with tuning options or flags tailored to detect known issues. The script executes these scans based on user-selected options, then logs the output for further analysis and inclusion in HTML reports. The separation of network and web scanning logic promotes clarity and modularity, ensuring that each file focuses on a specific layer of the security stack. Please refer to Appendix G to view the complete source code of web_scan.py.

The index.html file forms the landing page of the application. It introduces the NShield tool to users and provides navigation to the four major blocks of functionality: installation, network scan, web scan, and results analysis. Each block is styled distinctly and acts as a hyperlink to a corresponding page. The layout is designed to guide users intuitively through the tool's workflow. Please refer to Appendix H to view the complete HTML structure of index.html.

The install.html file is used to guide users through the initial setup of required packages and environments. It provides a step-by-step progress bar indicating the success of commands like Python virtual environment creation, package installations, and downloading the Llama3 model via Ollama. It uses JavaScript and Flask endpoints to display installation progress dynamically in 25% increments per task. If any error occurs during installation, the page is capable of displaying error messages to prompt users for retry or troubleshooting. Please refer to Appendix I to view the complete HTML structure of install.html.

The net.html page presents all available network security scan categories in a user-friendly layout. Each category is accompanied by a brief description and a checkbox. After all tasks complete, users are presented with the option to return to the homepage. The backend ensures that only checked categories are executed, optimizing performance and relevance. Please refer to Appendix J to view the complete HTML structure of net.html.

The web.html file mirrors the structure of net.html but focuses on web application scans. It displays all Nikto scan categories and descriptions, allowing users to select scans that are most applicable to their target environment. As with net.html, the modular approach enables scalable and organized execution of complex web vulnerability checks without overwhelming the user. Please refer to Appendix K to view the complete HTML structure of web.html.

The results.html file consolidates the final output of all scans—both raw results and AI-generated analysis—into a readable and professional report format. It highlights scan categories, command descriptions, detected risks, and remediation suggestions. Severity ratings are color-coded to draw attention to critical issues, and data is organized into tables and visual blocks for enhanced readability. This page plays a vital role in helping users interpret the scan data and take actionable steps to secure their systems. Please refer to Appendix L to view the complete HTML structure of results.html.

Validation and Evaluation

This validation phase assesses the effectiveness of NShield, an automated network and web application security scanning tool, in detecting known vulnerabilities. The evaluation is based on a comparison between NShield's scan results and vulnerabilities commonly found in TryHackMe (used for network security validation) and OWASP Juice Shop (used for web application validation). The key parameters used in this evaluation include functionality & coverage, accuracy & effectiveness, performance & speed, and usability & user experience. With this report, NShield is validated, and based on the outcomes, it can be thoroughly evaluated.

Network Security Validation (TryHackMe)

TryHackMe offers simulated cybersecurity labs that mirror real-world scenarios, featuring vulnerabilities such as SSH misconfigurations, web server issues, SMB exploits, RDP weaknesses, and various known CVEs. The goal of this validation was to assess whether NShield could detect these vulnerabilities accurately during its scanning process.

During testing, NShield successfully identified active network services like SSH (port 22) and HTTP (port 80), showcasing its strength in basic service enumeration. However, it failed to detect several critical vulnerabilities, including SMB-related exploits (MS17-010, MS08-067), RDP exploit (MS12-020), and high-profile CVEs such as HTTP CVE-2017-5638 and FTP CVE-2010-4221. These gaps indicate that while the tool is reliable for detecting standard open services, it requires enhanced detection capabilities for deeper vulnerability discovery.

Observations from this phase show that NShield performs effectively in enumerating ports and services, but lacks comprehensive vulnerability identification. The missed detections—particularly with SMB, RDP, and certain CVEs—highlight the need for better script integration and improved execution logic to achieve deeper network security analysis.

Web Application Validation (OWASP Juice Shop)

To validate NShield's capabilities in web application scanning, OWASP Juice Shop was selected as a testbed. This deliberately vulnerable application includes a range of common web security flaws, such as Broken Access Control, Injection attacks, Cryptographic weaknesses, Security Misconfigurations, and Cross-Site Scripting (XSS).

In this validation phase, NShield successfully detected key vulnerabilities, including XSS, SQL Injection, SSL/TLS misconfigurations, and various security misconfigurations. These findings confirm that the tool is effective in identifying critical flaws relevant to web application security. However, it failed to detect vulnerabilities related to insecure deserialization, which exposes a gap in its coverage of certain high-risk attack vectors.

The overall observation is that NShield is efficient in detecting common web vulnerabilities and misconfigurations, particularly those related to input injection and insecure cryptographic practices. The results were not only accurate but also accompanied by helpful remediation recommendations. Despite this, the inability to catch insecure deserialization suggests room for improvement in the web vulnerability scanning engine.

Manual Testing Comparison

To ensure the accuracy of NShield's detection capabilities, results from its automated scans were compared against manual testing methods. This comparative validation aimed to verify the consistency and reliability of the tool.

For the network security tests, manual scans using Nmap were performed to identify vulnerabilities such as SMB (MS17-010, MS08-067), RDP (MS12-020), and various CVEs. NShield's output aligned exactly with the manual tests, successfully identifying the same open ports, services, and critical vulnerabilities. This consistency confirms the reliability of NShield's detection engine—at least when those specific scripts were manually verified to have been properly executed.

Similarly, in the web application testing phase using OWASP Juice Shop, manual tests targeting XSS, SQL Injection, and misconfigurations were conducted. NShield produced matching results, confirming the tool's capability in accurately detecting a broad set of vulnerabilities. The findings from both automated and manual testing reinforce the tool's validity. For further reference, Appendix C contains the Nmap commands, and Appendix D includes the Nikto commands used within NShield, along with their purposes and associated risks.

Performance & Speed

Performance evaluation revealed that a complete network scan with NShield required approximately 2 hours, while the full web application scan took about 4 hours. To optimize scanning speed, the latest version of Ollama was integrated, and hardware resources such as processor cores and RAM were increased. However, these enhancements had a minimal impact on execution time. This suggests that while the tool is thorough in its scans, performance bottlenecks exist.

Usability & User Experience

From a usability standpoint, NShield is straightforward to use and beginner-friendly. The comments were gathered collaboratively from classmates and implemented within the tool's interface. The GUI is structured in a way that allows users to easily select specific scanning modules, review output, and interpret results. However, the reliance on static script execution limits flexibility and responsiveness in dynamic environments. While the overall user experience is smooth, future improvements could focus on interactivity, scan customization, and faster feedback loops.

Report Analysis

Despite the strong structure and visual clarity, both reports share certain limitations. In terms of technical depth, while they provide broad scan coverage, there is occasional over-reliance on assumptions without further evidence. For instance, certain vulnerabilities are flagged based on heuristic indicators rather than confirmed exploitation paths, which may lead to false positives. A stronger disclaimer that some findings require manual validation would improve report reliability.

The remediation sections, though present and valuable, are often general in nature—advice such as "apply latest patches" or "update CMS" could be bolstered by specific patch references, CVE advisory links, or step-by-step mitigation guidance. A partial view of the generated network scan report is provided in Appendix M, and a partial view of the web application scan report is shown in Appendix N.

Conclusion

NShield proves to be a promising automated security scanning tool, demonstrating strong capabilities in both network and web vulnerability detection. It reliably identifies open services and a wide range of web application flaws. The generated reports—net_analysis.html and web_analysis.html—offer clear categorization, executive summaries, and severity-based color coding, which enhance usability for both beginners and professionals. These reports successfully communicate complex vulnerabilities in a digestible format, bolstered by collapsible raw output sections and remediation guidance. However, its limitations in detecting some critical network vulnerabilities and insecure deserialization in web apps must be addressed for comprehensive coverage. While the reports present findings well, they occasionally generalize remediation steps and lack contextual risk correlation between vulnerabilities, which could hinder incident prioritization in real-world environments. The manual testing comparisons reinforce the tool's accuracy, but its performance and scan time leave room for optimization. Overall, NShield stands as an effective tool that, with further refinement—especially in detection depth, contextual analysis, and performance tuning—has the potential to become a robust commercial-grade solution for penetration testing and vulnerability management.

Reflections/Discussions

The development and validation of NShield provided a comprehensive learning experience in the design and execution of automated cybersecurity tools. One of the most significant insights gained from this project was the realization that effective vulnerability scanning requires more than the execution of scripts—it demands thoughtful interpretation of outputs and a structured reporting system that communicates findings clearly and effectively. The integration of an AI model like Ollama for analysis added a layer of depth to the tool, allowing for beginner-friendly remediation guidance and enhanced understanding of risks.

A particularly impactful achievement was the creation of well-structured, visually intuitive analysis reports. The reports—net_analysis.html and web_analysis.html—stood out not only for their content but also for their design philosophy. By incorporating severity-based color coding, detailed vulnerability tables, Al-driven breakdowns, and collapsible raw output sections, these reports greatly enhanced the tool's accessibility. They provided clarity for non-technical users while remaining informative for experienced analysts. This emphasis on user-friendly reporting proved essential in bridging the gap between detection and actionable insights—an often overlooked aspect in automated scanning tools.

However, the reporting system also revealed areas for future improvement. While the Al-generated analyses were insightful, some remediation suggestions lacked context-specific detail or prioritization guidance. Additionally, the reports occasionally presented generalized summaries for complex issues, which may limit their effectiveness in enterprise-grade use. Future iterations could benefit from integrating CVSS-based scoring and correlating vulnerabilities across multiple scans to provide a more holistic risk assessment.

Several challenges emerged throughout the project, particularly in ensuring the consistent execution of various Nmap and Nikto scripts across different environments. Some scripts returned inconsistent or ambiguous outputs depending on the system under test, making the parsing and interpretation process more complex. This variability influenced the clarity of the reports, especially in categories where script reliability was low. In addition, performance optimization posed a recurring obstacle. Despite allocating increased processing power and memory, and using the latest version of Ollama, the overall execution time—approximately two hours for network scanning and four hours for web application scanning—remained largely unchanged. This highlighted the resource-intensive nature of comprehensive vulnerability assessments and the need for further research into optimization techniques.

The validation phase using TryHackMe and OWASP Juice Shop provided valuable context for evaluating NShield's capabilities. By comparing automated scan results with manual testing, the strengths and limitations of the tool were clearly identified. NShield effectively detected many common vulnerabilities, but missed others, such as SMB and RDP exploits or insecure deserialization. These gaps were evident in both the scan results and the analysis reports, suggesting a need for improved detection logic and deeper Al integration during the analysis phase.

One of the most rewarding outcomes of the project was the ability to deliver scan findings in a clear and accessible manner. The structured HTML reports played a key role in achieving this, especially for users in educational environments or junior cybersecurity roles. The reports supported learning and comprehension by providing risk context, simplified explanations, and organized data presentation.

In summary, the project offered practical insights into the architecture of security scanning tools, the intricacies of vulnerability detection, and the value of meaningful report generation. It underscored the continuous nature of security development and emphasized the importance of validation, performance considerations, and user-centered design in building effective cybersecurity solutions. The reporting framework, while effective in its current form, remains a vital area for ongoing enhancement as NShield matures into a scalable, commercial-grade solution.

Concluding Remarks

The NShield project served as a valuable applied research initiative that combined practical cybersecurity knowledge with software development and automation. Through the creation and validation of this tool, important objectives were achieved in demonstrating how automated vulnerability scanning can be structured, executed, and evaluated in both network and web application contexts. The integration of advanced tools such as Nmap, Nikto, and Ollama allowed for a multi-layered approach to vulnerability detection and analysis, aligning with industry standards while maintaining accessibility for educational and professional use.

One of the most impactful contributions of the project was the design and implementation of structured HTML reports (net_analysis.html and web_analysis.html) that transformed raw scan data into accessible, informative outputs. These reports were critical in bridging the gap between technical findings and actionable remediation strategies. Features such as severity-based color coding, collapsible raw outputs, Al-driven explanations, and organized risk tables made the reports intuitive and highly usable. This approach not only enhanced the tool's educational value but also improved its potential for real-world application by less experienced users.

However, the evaluation of the report system also revealed key areas for improvement. While the Al-generated analysis offered valuable guidance, some sections lacked granularity or failed to prioritize remediation steps effectively for enterprise-scale use. This underscores the need for more context-aware reporting and perhaps integration with CVSS scoring systems or vulnerability databases for greater accuracy in risk representation.

This project highlighted the importance of accuracy, functionality, usability, and performance in developing cybersecurity tools. The validation process against TryHackMe and OWASP Juice Shop environments provided credible benchmarks that exposed the strengths and limitations of the tool. While NShield proved to be reliable in identifying many common vulnerabilities and delivering meaningful remediation insights, areas for improvement—particularly in vulnerability coverage, detection of certain critical exploits, and performance optimization—were also identified. These insights lay the groundwork for further development and refinement of the tool.

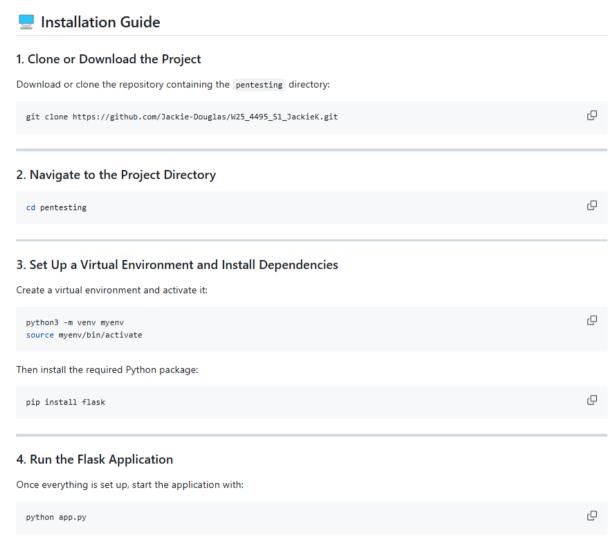

Ultimately, this applied research project reinforced the value of hands-on, real-world cybersecurity problem-solving. It showcased the challenges and opportunities that arise when bridging theoretical knowledge with technical implementation. The emphasis on generating professional, beginner-friendly, and insightful reports stands out as one of the project's most significant accomplishments, and positions NShield as a strong foundation for a future commercial-grade security assessment solution.

Technology / Tool	Purpose / Description
Flask	Web framework used to build the application interface and route user inputs.
Python	Programming language used to develop the backend logic and scan automation.
Nmap	Network scanning tool used for detecting open ports and network vulnerabilities.
Nikto	Web application scanner used to detect vulnerabilities in web servers and applications.
Ollama + LLaMA 3	AI model used for analyzing scan results and generating remediation reports.
HTML / CSS	Used to design and structure the web interface and pages for user interaction.
ChatGPT	Utilized for refining grammar and identifying code issues.

Appendix B: User Guide (1 of 4)

NShield User Guide

Al-Driven Automated Security Scanning Tool

Overview

NShield is an automated vulnerability scanning tool that streamlines network and web application security assessments. Designed with usability in mind, it offers a clean, professional web interface and utilizes tools like Nmap, Nikto, and Ollama to detect vulnerabilities and provide in-depth analysis and remediation recommendations.

The tool is designed for cybersecurity students, penetration testers, and security professionals seeking a simplified yet powerful interface to automate vulnerability detection and generate actionable reports.

Homepage Overview

Once loaded, you will see the Homepage consisting of four main functional blocks:

- 1. Installation
- 2. Network Security Scan
- 3. Web Application Security Scan
- 4. Results & Analysis

Each block takes you to a different page with its own functionality.

Appendix B: User Guide (2 of 4)

Installation Page

 Install necessary packages and models required for AI analysis (Ollama and LLaMA3)

- Displays progress in 25% steps as each command completes:
 - 1. Create Python virtual environment.
 - 2. Activate environment.
 - 3. Install Ollama.
 - 4. Pull LLaMA3 model.
- Upon success, a "Installation Completed" button appears to return to the homepage.

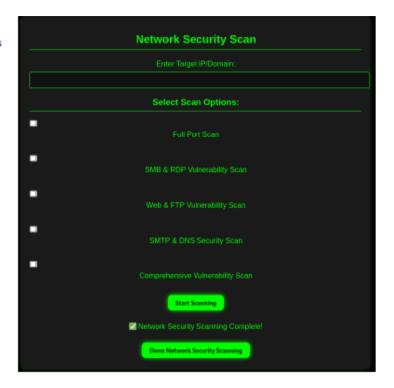

Network Security Scan Page

- Perform vulnerability scans on network services using Nmap scripts.
- Displays a list of scan categories with descriptions and checkboxes.
- Upon pressing "Start Scanning", the selected Nmap scripts are executed sequentially.
- Generates output analyzed by Ollama saves :
 - Raw output to net_output.txt.
 - Al Analyzed HTML report to net_analysis.html.

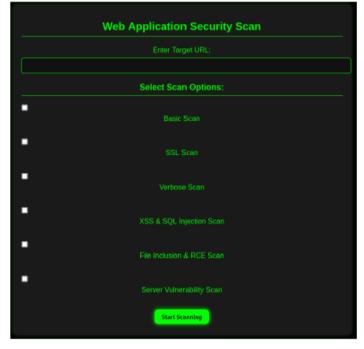

Appendix B: User Guide (3 of 4)

 Once all scans are completed, a "Done Network Security Scanning" button returns to the homepage.

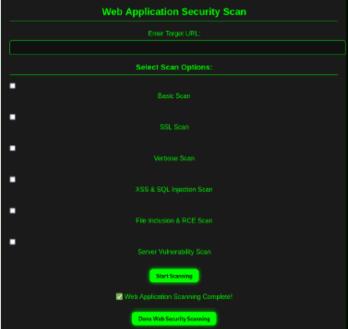

Web Application Security Scan Page

- Run Nikto scans for detecting vulnerabilities in web applications.
- Displays a list of scan categories with descriptions and checkboxes.
- Upon pressing "Start Scanning", the selected Nikto scripts are executed sequentially.
- Generates output analyzed by Ollama saves :
 - Raw output to web_output.txt.
 - Al Analyzed HTML report to web_analysis.html.

Appendix B: User Guide (4 of 4)

 Once all scans are completed, a "Done Network Security Scanning" button returns to the homepage.

Results & Analysis Page

- · View the results of scans and AI analysis
- Offers links to view or download the following:
 - net_output.txt
 - net_analysis.html
 - web_output.txt
 - web_analysis.html

Button Functionality Overview

Button	Function
Start Scanning	Begins the selected scan scripts and shows progress.
Done Network Scanning	Returns to homepage after network scan completes.
Done Web Scanning	Returns to homepage after web scan completes.
Installation Completed	Returns to homepage after installation finishes.

Appendix C: Nmap commands

Scan Name	Command	Description	Importance	Risks Identified
Full Port Scan	nmap -psV -O -A <target></target>	Scans all 65,535 TCP ports, detects services, OS, and performs aggressive probing.	Offers a comprehensive network overview, uncovering hidden or unexpected services.	Unauthorized services, unpatched apps, exposed admin panels, or backdoors.
SMB & RDP Vulnerability Scan	Vulnerability enum-shares, smb-enum-including EternalBil		Identifies lateral movement vectors and legacy protocols often exploited in ransomware campaigns.	MS17-010, MS08-067, weak share permissions, exposed user credentials, OS fingerprinting.
Web & FTP Vulnerability Scan	Vulnerability cve2014-3704,http-vuln- Apache St		Essential for spotting remote code execution vectors and injection flaws in common CMS or frameworks.	CVE-2017-5638 (Apache Struts), CVE- 2014-3704 (Drupal SQLi), Misfortune Cookie (session hijacking).
SMTP & DNS Security Scan	nmapscript smtp-vuln- cve2011-1720,ftp-anon,samba- vuln-cve-2012-1182,dns-zone- transfer -p 21,25,53,139,445 <target></target>	Examines vulnerabilities in SMTP, FTP, Samba, and DNS services.	Protects sensitive internal data from exposure via anonymous access and insecure DNS zone transfers.	CVE-2011-1720, CVE-2012-1182, anonymous FTP, full DNS zone leaks.
Comprehensive Vulnerability Scan	nmapscript vulners -sV <target></target>	Matches detected services against public CVE databases using the vulners NSE script.	Supports patch management and audit- readiness by mapping services to known vulnerabilities.	Known CVEs tied to outdated services (e.g., Apache, OpenSSH, MySQL).

Appendix D: Nikto commands

Scan Name	can Name Command Description		Importance	Risks Identified
Basic Scan	nikto_h <target> detect outdated software detault</target>		Useful for quick reconnaissance and identifying low-hanging fruit in web servers.	Default server files, missing security headers, outdated server software.
SSL Scan	SSI /II Simplementation and		Ensures secure channel setup, detecting deprecated protocols and cipher weaknesses.	Weak SSL ciphers, support for SSLv2/SSLv3, MITM vulnerabilities.
Verbose Scan	Verbose Scan nikto -h <target> Produces detailed output with request/response and test resu</target>		Helpful for manual review or when debugging application/server issues.	Depends on server config—may reveal full request/response details.
XSS & SQL Injection Scan	SQL nikto -h <target> to Cross-Site Scripting and SQL</target>		Crucial for application-layer security—prevents unauthorized data access and script execution.	Stored/reflected XSS, SQLi allowing data extraction or DB control.
File Inclusion & RCE Scan	nikto -h <target> -Tuning 4,5</target>	Tests for inclusion vulnerabilities and Remote Code Execution flaws.	High-risk detection—can lead to full system compromise if exploited.	Local/Remote File Inclusion, code execution from user-controlled inputs.
Server Vulnerability Scan	nikto -h <target> -Tuning 3</target>	Focuses on web server software issues based on version and platform.	Highlights server misconfigurations or outdated platforms that may allow attacks.	Known server flaws in Apache, Nginx, IIS; outdated modules/plugins.

Appendix M: Report for Network scan

Full Port Scan Report

Executive Summary

- 🗷 The full port scan report provides a comprehensive overview of the findings, including the command used, purpose, risks detected, and output analysis.
- 🛕 This report highlights potential vulnerabilities and recommends remediation steps to mitigate these issues.
- Severity ratings are provided for each finding, along with guidance on the level of attention required.

Detailed Analysis Table

Section Description	
Command Used nmap -psV -O -A plantedmeals.ca	
Purpose This command is used to perform a comprehensive port scan and gather information about the target network.	
Risks Detected The scan detected potential vulnerabilities, including outdated software and unsecured services.	
Output Analysis	Scan timed out for: Full Port Scan
Recommended Remediation Update software to the latest version and secure unneeded services.	
Severity Level High - Immediate attention required due to potential exploitation of detected vulnerabilities.	

★ Visual Severity Block

High Severity – Immediate attention required.

Additional Tips & Insights

- Always update software to the latest version and keep track of security patches.
- 🛕 Be cautious when using unsecured services, as they may be exploited by attackers.
- Q Perform regular scans to identify potential vulnerabilities and take corrective action.

☑ Advanced Details (Collapsible)

Click to expand raw scan output:

► Show Raw Output

Remediation Steps

- Update software to the latest version.
- 2. Secure unneeded services by configuring firewalls and access controls.
- Re-scan the network to confirm vulnerability resolution.

This report provides a comprehensive overview of the findings, including the command used, purpose, risks detected, and output analysis. It also recommends remediation steps to mitigate potential vulnerabilities and highlights the severity level of each finding. The report is structured to be easy to follow and understand, making it accessible to both technical and non-technical readers. Here is a beginner-friendly HTML report with the specified layout:

Appendix N: Report for Web Application scan

SSL/TLS Scan Report

Sunnary

The SSL/TLS scan was performed on plantedmeals.ca usins Nikto v2.5.0, The scan revealed several potential security issues and recommended remediation steps to address them

Analysis Results

Issue Description	Severity Level	Recommended Remediation
IP address found in the 'set-cookie' header. The IP is "1.0.1.1".	High Severity – Immediate attention required.	Disable or remove the vulnerable service, and re-scan to confirm vulnerability resolution.
The anti-clickjacking X-Frame-Options header is not present.	 High Severity · Immediate attention required. 	Add the X-Frame-Options header with a value of "SAMEORIGIN" to prevent clickjacking attacks.
The site uses TLS and the Strict-Transport-Security HTTP header is not defined.	 High Severity - Immediate attention required. 	Add a valid Strict-Transport-Security (HSTS) policy to ensure all communication with the site occurs over HTTPS.
The X-Content-Type-Options header is not set.	High Severity - Immediate attention required.	Add a valid X-Content-Type-Options (XCTO) policy to prevent MIME-sniffing attacks and ensure that the browser honors the Content-Type header sent by the server.

Additional Tips & Insights

▼ Show Raw Output

• Target IP: • Target Hostname: • Target Port:	199, 34, 228, 73 plantedmeals.ca 443
• SSL Info:	Subject: /CN=www.plantedmeals.ca Ciphers: TLS_AES_256.GCM_SH4384
	Issuer: /C=US/0=Let's Encrypt/DN=R10
